

App Launch Prep and Plan

App Overview and Purpose

I have chosen to work on an inventory tracker mobile application designed to help users manage warehouse inventory from a phone or tablet. The app allows users to create an account, log in, choose whether to allow SMS alerts, add inventory items, view current stock, update item quantities, and remove items that are no longer needed. The main target users are warehouse employees, small business owners, stockroom workers, and managers who need a simple way to track inventory while moving through a workplace. The launch goal is to provide a clean and functional inventory tool that supports the required features from the project scenario while staying easy for users to understand.

App Description and Icon

The app store description will explain that the inventory tracker helps users manage stock levels through a simple current inventory screen. It will mention that users can add an item, select an item row, increase or decrease the quantity, type an exact quantity, and remove selected items. It will also show a low stock alert feature and the optional SMS notification feature. The icon will be simple and professional, such as a box, shelf, or clipboard with a checkmark. An icon like that, matches the purpose of the app because it clearly corresponds with inventory tracking, organization, and completed stock checks.

App Permissions

The app runs on Android version 14 / API 34 which is the current testing setup, but should be tested on Android's most current version. It uses standard interface elements such as text fields, buttons, a scroll view, and a table style inventory display, so it should work well on different

android devices. Because Android updates can change permissions, layouts, and app behavior, the app should be tested on newer Android versions before a launch. The app should only ask for permissions that directly support its features. The main optional permission is SEND_SMS, which is used for low stock text alerts. If the user declines SMS permission, the inventory features will still work.

Testing and Launch Checklist

During development, the app was tested thoroughly from the beginning and all the way to the end. The login and create account buttons were tested with both valid and missing information. The database was tested by adding inventory items, updating quantities, removing items, and confirming that the items appeared in the Current Inventory list. The update features were tested by selecting a row, using the plus quantity button, using the minus quantity button, and typing a new quantity before pressing the keyboard Done/checkmark button. Low stock inventory was tested by setting an item quantity to three or lower and then to zero. SMS behavior was tested by allowing and declining SMS permission to make sure the app still worked either way. But, before an actual launch, these tests would have to be repeated on different Android devices/versions.

Monetization

I would not include ads because advertisements just don't look professional. My initial plan would be to release the app as a free prototype or basic tool. If the app were expanded later, a one time paid upgrade would be my choice. This would come with more features such as barcode scanning, report exporting, cloud backup, multiple users, and reorder reminders. Once I add more features and functions to this app. I'd also like to add more support which would focus on fixing bugs, improving login security, adding better database protection, and refining the

interface based on user feedback. Which would give this launch plan for the app a more realistic path from just a class project prototype to a more complete inventory management app.
